#### LECTURERS AND AUTHORS

#### CHAPTER

- 1. Introduction to Design and Analysis (W.J. Garland, AECL/EC)
- 2. Introduction to Safety Analysis (V. Snell, AECL/EC)
- 3. Heat and Mass Transfer and Two-Phase Flow I (J.S. Chang, McMaster)
- 4. Heat and Mass Transfer and Two-Phase Flow II (R.L. Judd, McMaster)
- 5. Single and Two-Phase Flow Modelling I (W. Brimley, AECL/EC)
- 6. Numerical Methods I (B. McDonald, AECL/WSNRE)
- 7. Single and Two-Phase Flow Modelling II (B. McDonald, AECL/WSNRE)
- 8. Computational Analysis of Multidimensional Flow (M. Carver, AECL/CRNL)
- 9. Numerical Methods II (P.T. Wan, McMaster)
- 10. Process Design I (W.J. Garland, AECL/EC)
- 11. Operational Considerations (R. Bassermann, Ontario Hydro)
- 12. Process Equipment (W. Brimley, AECL/EC and D. Meranda, Ontario Hydro)
- 13. Process Control (Q.B. Chou, Ontario Hydro)
- 14. Chemistry and Materials of Thermalhydraulic Loops (D. Barber, AECL/EC and R. Fleck, Ontario Hydro)
- 15. Safety Analysis I, Thermohydraulics (N. Spinks, AECL/EC)
- 16. Safety Analysis II, High Temperature Transient Fuel Channel Behaviour (P.D. Thomson, H.S. Waldman, C.L. Swift-Schulz, D. Caswell, S. Girgis, AECL/EC)
- 17. Single and Two-Phase Flow Diagnostics and Monitoring (W. Brimley, AECL/EC and J.S. Chang, McMaster)
- 18. Process Design II (W.J. Garland, AECL/EC)
- 19. Safety Analysis III, Containment Analysis (D. Pendergast, W.M. Collins, AECL/EC)

#### WORKSHOP CO-CHAIRMEN

Workshop I - Design (W. Garland, AECL/EC and D. Meranda, Ontario Hydro)

Workshop II - Safety (W. Midvidy, Ontario Hydro and V. Snell, AECL/EC)

### THE CANDU POWER REACTOR SYSTEM: A PREFACE

The CANDU nuclear power reactor system has been under development since the early 1950's by Atomic Energy of Canada Limited (AECL) in collaboration with Canadian industry. CANDU stands for CANada Deuterium Uranium indicating that the reactor uses heavy water or deuterium oxide as moderator, and natural uranium as fuel. The success of the system is indicated by the record breaking performance of the Pickering Generating Station of Ontario Hydro on the shores of Lake Ontario close to the metropolitan area of Toronto (Fig. P1).

The four 500 MWe Pickering reactors are known as CANDU-PHW units, to indicate that the coolant is heavy water under pressure. Although the PHW system has received the most attention so far and has been developed to a commercial stage at Douglas Point Pickering and Bruce, other versions are under consideration. For example, a prototype station using light water as coolant was started up in 1971 at Gentilly, Quebec. Another version of CANDU is the OCR for Organic Cooled Reactor. A research reactor using an organic liquid coolant has been operating since 1965. Higher temperatures are a feature which could be of great value when other fuel cycles are being considered or for applications where high temperature steam is required.

The outstanding advantage of the CANDU system is its ability to operate with natural uranium fuel. This permits the purchase of uranium feedstock on the world market without limitations of enrichment services. In addition, the CANDU system extracts more electrical energy per unit of uranium feedstock than any other commercially proven reactor system.

Canada has abundant reserves of uranium but no enrichment plant so that the ability to utilize natural uranium fuel is particularly attractive from a national standpoint, both in terms of balance of payments and freedom from external political and economic pressures. These considerations have been significant factors in the longstanding support given to the development of the CANDU system by the Federal Government.

The major commercial utilization of the CANDU system in Canada has been within the Ontario Hydro system. The large size of this system, the absence in Ontario of significant fossil fuel reserves, and the harnessing of most of the available hydraulic sites, has led Ontario Hydro to commit a series of large multi-unit CANDU stations. Over 35% of electrical demand in Ontario is generated by nuclear power.

Hydro-Quebec's initial entry to the nuclear power field was via the construction and subsequent operation of the Gentilly-1 nuclear power station. This station, owned by AECL, employs the prototype CANDU-BLW reactor. While Quebec still has substantial unharnessed hydraulic reserves (primarily in the James Bay region), Hydro-Quebec has constructed a 600 MWe CANDU station in their system at the Gentilly site.

The potential attractiveness of this size led AECL to adopt it as a standard unit. Substantial success has already been achieved in marketing this unit design. In addition to Gentilly-2 being constructed by Hydro-Quebec, AECL has a contract (in partnership with an Italian company) to supply one unit to Argentina (Cordoba). The New Brunswick Electric Power Commission

# WORLD POWER REACTOR LIFETIME PERFORMANCE

| 1  | CANADA     | Pickering-2        | 542 MW | 84.5% |
|----|------------|--------------------|--------|-------|

has built one unit at a site near St. John (Point Lepreau), and another unit is under construction in the Republic of Korea. The four CANDU-600's are at various stages of completeness with Point Lepreau presently approaching full power.

Summaries for performance and penetration of CANDU reactors are given in Figs. P1, P2, and P3. While CANDU carries an initial cost penalty due to the high price of heavy water, this is more than offset during an operating life-time due to cheap natural uranium fuel, efficient burn-up and inherent safety features of the reactor. Indeed the CANDU PHW reactor design with its heavy water moderator, natural uranium fuel and pressure tube concept has certain characteristics that obviate the need for a high strength pressure vessel. Instead, the pressure boundaries are the pressure tubes which are considerably simpler to manufacture to the required quality. Further, experimental evidence and station performance indicates that pressure tubes will leak before they break since their thickness is much less than the critical crack length. Such leaks can be readily detected by monitoring the moisture content and the pressure in the gas annulus between the pressure tube and the calandria tube. This is done on a continuous basis. In addition, ultrasonic scanning devices are mounted on the fuelling machine for periodic inservice inspection of the pressure tubes.

The pressure tube design permits the heat transport system to be subdivided into two separate coolant circuits (loops). In the case of a hypothetical loss of coolant accident, this design feature restricts the consequences of the loss of coolant accident to just one of the loops. This simplifies the design and considerably reduces the burden on the emergency injection and the containment system design.

All reactivity devices are located in guide tubes positioned in the low pressure moderator environment. Thus, there exists no mechanism for rapid ejection of any of these reactivity devices, nor can they drop out of the core. The maximum reactivity rates achievable by driving all control reactivity devices together in the wrong direction is about 0.35 mk per second and well within the design capabilities of the protective systems.

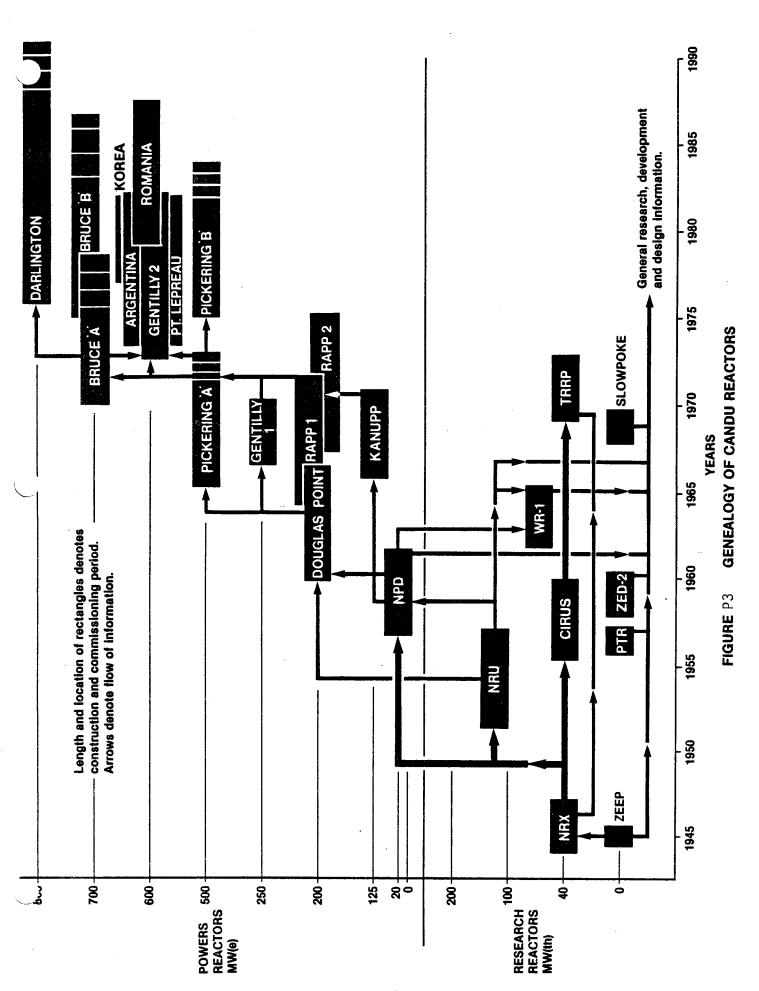

Fuel, coolant and moderator are arranged in a square lattice with a 28.6 cm pitch. This is a near optimum geometry from a reactivity standpoint. Even if all fuel channels were either pushed apart or brought together for whatever reason the net reactivity increase would be at most, 1 milli-k where k is the neutron multiplication constant; and this only for the ideal case of uniform rearrangement. This is, of course, physically impossible. For the case where one, or a few fuel channels are displaced, the net reactivity would at worst not be affected at all or it would decrease, thereby shutting down the reactor. Also, since a lattice of natural **uranium** and light water cannot be made critical in any concentration, there can be no criticality problems in the spent fuel bay of CANDU reactors.

The pressure tube design also makes on-power fuelling a possibility. On-power fuelling results in a reactor with very low reactivity control requirements. Typically, the reactivity decay rate in 600 MW(e) CANDU PHW reactors is about 0.4 mk per day. This is compensated by fuelling about

two channels per day. In addition, the pressure tube concept provides an excellent opportunity for locating fuel defects and the on-power fuelling permits the removal of defective fuel as soon as it is detected. This helps to keep the heat transport system essentially free from fission product activity.

Finally, the separation of the moderator from the high pressure heat transport coolant allows the moderator to act under certain circumstances as an additional heat sink for the fuel decay heat, e.g., where one might hypothesize a failure or impairment in the emergency core cooling system following a primary loss of coolant accident.

Thermalhydraulics, which is the central theme of this course, is concerned with safe and effective heat removal from the reactor core for power production. The basic CANDU design, while favourable to both safety and efficiency, must be studied in detail for the development of optimal structures and strategies. The following lecture notes represent the state-of-the-art of this challenging branch of nuclear engineering.

#### GLOSSARY OF ABBREVIATIONS AND ACRONYMS

AE Acoustic Emission

AECB Atomic Energy Control Board

AESOP Atomic Energy Simulation of Optimization

ASDV Atmospheric Steam Discharge Valve

ASSERT Advanced Solution of Subchannel Equations in Reactor Thermalhydraulics

ASTM American Society for Testing Materials

BLC Boiler Level Control
BLW Boiling Light Water

BOILER Boiler

BPC Boiler Pressure Controller

CCP Critical Channel Power

CHF Critical Heat Flux
CPR Critical Power Ratio

CRNL Chalk River Nuclear Laboratories

CRT Cathode Ray Tube

CSA Canadian Standards Association
CSDV Condenser Steam Discharge Valve

CSNI Canadian Standards for the Nuclear Industry

DBE Design Base Earthquake
DCC Digital Control Computer

DF-ET Drift Flux-Equal Temperature
DF-UT Drift Flux-Unequal Temperature
DNB Departure from Nucleate Boiling

ECC Emergency Core Cooling

ECI Emergency Core Injection

EFPH Effective Full Power Hours

EVET Equal Velocity Equal Temperature

EVUT Equal Velocity-Unequal Temperature

EWS Emergency Water Supply FBR Feed, Bleed and Relief

FP Full Power

HEM Homogeneous Equilibrium Model

HTS Heat Transport System

HWP Heavy Water Plant

HYDNA Hydraulic Network Analysis
I&C Instrumentation and Control

IBIF Intermittent Buoyancy Induced Flow

ICRP International Commission on Radiological Protection

LOC Loss of Coolant

LOCA Loss of Coolant Accident

LOC/LOECC Loss of Coolant with Coincident Loss of Emergency Core Cooling

LOP Loss of Pumping

LOR Loss of Regulation

MCCR Ministry of Corporate and Consumer Relations

MCS Maintenance Cooling System

MHD Magneto hydrodynamics

milli-k See p. 13-7

NPD Nuclear Power Demonstration

NPSH Net Positive Suction Head

NUCIRC Nuclear Circuits

OECD Organization for Economic Co-operation and Development

PGSA Pickering Generating Station A

PHTS Primary Heat Transport System

PHW Pressurized Heavy Water

PHWR Pressurized Heavy Water Reactor

PRESCON2 Pressure Containment

QA Quality Assurance

RAMA Reactor Analysis Implicit Algorithm

R&M Reliability and Maintenance

RB Reactor Building

rem rontgen or rad equivalent mammal

RIH Reactor Inlet Header
ROH Reactor Outlet Header

RTD Resistance Temperature Detectors

SDM Safety Design Matrices

SOPHT Simulation of Primary Heat Transport

SRV Safety Relief Valve

TMI Three Mile Island

TOFFEA Two Fluid Flow Equation Analysis

UVUT Unequal Velocity Unequal Temperature

VB Vacuum Building
VC Vacuum Chamber

WNRE Whiteshell Nuclear Research Establishment
